PREFACE

Vermont Population Projections, 1985-2000 has been prepared to serve the planning needs of state and local government. These projections succeed The People Book (1979) and Interim Revised Population Projections (1982). They provide a base from which to gauge what the future may bring. Careful examination and analysis of the projections will help administrators in all areas of government prepare for tomorrow's needs - schools, water and sewer, care for the elderly, energy, the incarcerated, the labor force, the economy, housing, health care and many other areas. The projections can also be useful for business people to examine the future demand for their services.

The high and low projections are intended to provide a usable range of numbers for analytical and planning purposes. With population projected in a range rather than a fixed number, all users can focus their attention on the issues or impacts that will develop within the range of numbers. The range represents conservative assumptions about future rates of migration. The rates of net migration used are based on our best estimates of the past conditions and a likely future. A pleasant living environment and economic opportunity are two forces that encourage people to locate in Vermont. We assume that these two positive forces will continue.

These population projections will be used in the Vermont Vital Trends Project. The projections serve as base for analytical efforts in identifying the major issues facing state government over the next 18 years.

The State Planning Office will provide assistance to anyone engaged in a project that requires assessment of population projections. The contact person is David Healy (802-828-3326). For any questions concerning the methods used to produce these projections, contact Walter L. Cooley at the Department of Health (802-863-7300).

INTRODUCTION

This report presents two series of age-sex projections of the population of Vermont and its counties, plus total projections of the towns and cities, to the year 2000. A summary of the two series for each county are presented in Table A.

TABLE A

PROJECTIONS OF THE POPULATION OF VERMONT TO 2000 BY COUNTY

	1980 CENSUS	PROJECTION TO 2000 LOW SERIES		PROJECTION TO 2000 HIGH SERIES	
		PROJECTED POPULATION	% CHANGE 1980-2000	PROJECTED POPULATION	% CHANGE 1980-2000
STATE	511,456	611,806	19.6	652,552	27.6
Addison	29,406	36,793	25.1	39,709	35.0
Bennington	33,345	39,503	18.5	42,479	27.4

Windham	36,933	44,033	19.2	46,476	25.8
Windsor	51,030	58,095	13.8	61,172	19.9

The high series was produced assuming that migration rates through the year 2000 would continue at the rate observed during 1970-80. The net migration rate[1] during the decade of the 70's was the highest rate observed in the past 80 years in Vermont. For the low projection series, migration rates were reduced in order to obtain a labor force population approximating the economic projections developed by the U. S. Department of Commerce. In addition, the low series net migration rate is nearly identical to that observed in the latter half of the

[1]Net migration is computed by calculating the difference in population size over a time interval, then subtracting the contribution due to natural increase. Natural increase is calculated by subtracting the number of deaths during the time interval from the number of births occurring in the same interval.

decade, 1975-80. The choice of which projection series to use for a given application may be facilitated by assessing national and local economic trends in effect at the time this publication is consulted, as well as anticipated future economic activity. In general, high levels of economic activity are more likely to result in the attainment of the high projection series, and vice-versa. The consequences of overestimation versus underestimation of the population should also be weighed when deciding which series to use.

For the state population, the high series exceeds the low series by only 1.7% in 1985, increasing to 6.7% by 2000 (Table B). For the individual counties, the high and low series are very similar for Chittenden and Franklin Counties, but vary as much as 16% for Grand Isle and Orange Counties.

TABLE B

PERCENTAGE DIFFERENCE OF THE HIGH PROJECTION SERIES OVER THE LOW SERIES, BY COUNTY, 1985-2000

	1985	1990	1995	2000

Windsor	1.3	2.5	4.0	5.3

SUMMARY OF FINDINGS

Vermont's total population is projected to increase by 28% to 652,500 from 1980 to 2000 by the high series, or by 20% to 611,800 according to the low series (Table A). The fastest growing segment of this population is the cohort aged 35-64 years, which is projected to increase by 75.7% or 62.7% by the two series (Figure 2). The growth of this cohort is due to the aging of the post World War II baby boom and to relatively high in-migration rates. The only other cohort growing faster than the state total population is the 65+ group, projected to

increase at approximately 30-34%. The number of children aged less than 5 years old is expected to peak by 1990, then decline slowly. Youths aged 5-19 are expected to decline in number until 1985-90, and then grow somewhat due to increases in the birth rates that occurred during the late 1970's and early 1980's.

The young adult cohort, aged 20-34, is the only group expected to decline in number over the projection period. The size of this cohort will peak between 1985 and 1990, and then decline notably. Their decline from 1980 to 2000 will be appproximately 3.5% to 10.3%, according to the high and low projection series. This decline is due to the movement of the post World War II baby boom into the 35-64 year cohort, and to the large decline in birth rates in the 1960's and early 1970's. These changes in the age distribution of the Vermont population for males and females are displayed in a population pyramid (Figure 3).

Differences in growth rates are anticipated among counties (Figure 4). A significant regression of the logarithm of 1980 population size versus projected percent increase showed that smaller counties are expected to exhibit a greater percent growth than are larger counties. Three counties show different projected growth rates than would be expected on the basis of their 1980 population size. Essex County will grow more slowly, and Lamoille and Orange Counties will grow more rapidly than expected.

An examination of the components of population growth (Table C) shows that, according to the low projection series, Vermont will increase by 22,094 persons from 1995 to 2000. Thirty-three percent (7,262 persons) of this increase will be due to net migration. Net migration is expected to vary substantially from county to county. For example, over half of the total increase in the more rapidly growing counties of Grand Isle, Lamoille and Orange will be due to migration. Migration will also be greater than half the total growth of two slower growing counties, Bennington and Rutland, due to a high death to birth ratio causing a relatively low natural increase. Less than 15 percent of Chittenden and Franklin County's growth will be net migration.

Of the 5,878 net in-migrants to Chittenden County that occurred between 1970-1980, 30% (1,820 persons) were due to expanded student enrollments in the various colleges. During the projection period the number of students attending institutions of higher education in Chittenden County are assumed to remain generally constant. As a result, the net migration rates applied to Chittenden County produce a reduced share of the total net in-migrants to the state during the projection periods. A similar phenomenon exists in those counties with sizeable college populations.

SUMMARY OF METHODOLOGY

The cohort-component demographic model was used to produce a high and low series of age-sex projections, using the 1980 census data as the base. First the 1980 census was adjusted to exclude the excess college age population. Then each five-year age-sex cohort was survived over 5-year intervals, and five years of births were projected and survived. At 1990 and at 2000, the survived population was migrated using two methods. The first (high series) used 10-year net migration rates, developed from the 1970 and 1980 census and 10 years of vital statistics data. The second method (low series) was based on reduced migration rates which yielded conservative economic projections of a target labor force for each period. Interpolation techniques yielded the 1985 and 1995 migrated populations. Finally a projected excess college age population was restored to complete the projections.

State and county populations were projected separately. The county projections were then summed, cohort by cohort, and compared with the state projection. Agreement was very close, so the sum of the counties is published as the state total projection.

The starting point for state and county fertility and mortality rates was 1980. These rates were projected to change over time at the same rate as the U.S. Bureau of the Census projection of the rates for the U.S. White population.

Town total projections were computed by projecting the changing ratios of towns to the county total. These ratios were multiplied by the projected county total populations to produce town projections.

A detailed methodology is presented in the appendix.

APPENDIX

DETAILED METHODOLOGY

The cohort-component model was used to produce the state and county age-sex projections. Each component of population change - births, deaths, and net migration - was projected separately for each five-year cohort. These projections began with the 1980 census data for Vermont. The population was projected by applying a set of survival rates by age and sex, and net migration rates by age and sex. Births were developed by projecting Vermont fertility rates, then multiplying by the average number of females during the projection period. A more complete discussion of each of the components follows.

1. College Age Adjustment

First, a "normal resident" population base was created, to be used in survival, migration and fertility calculations. The college age population, consisting of a portion of the 18-24 population, was subtracted from the Census population. The college age population was projected separately from the normal resident population, because of substantial differences in fertility and net migration rates between these two populations. College age projections were accomplished using projections of the 18-24 population and Vermont colleges' expected enrollments.

Since good data on the number of college students by sex, age and place of origin was unavailable, adjustments to the 15-19 and 20-24 cohorts were developed graphically. A plot of the U.S. population by sex and single years of age shows a relatively straight line between ages 17 and 27. This was assumed to be the expected, or normal, population pattern in the absence of migration of college age youth. Single years of age 12-30 were plotted for each sex for the state and for each county and a straight line from age 17 to age 25 was calculated. The excess or deficient population for each age 18 to 24 was calculated and grouped into 18-19 and 20-24 cohorts as the 1980 college age adjustments.

Note that the college age adjustment represents the excess of college age persons in the state over those departing the state, and the clustering of young people in the college counties at the expense of non-college counties. These individuals are primarily college students, but also include young people leaving or entering the area for work, military service, or travel.

2. Component Assumptions and Procedures

a. Mortality component.

Sex-specific life tables were produced for the state and for each county, using 1978-81 Vermont resident deaths and the college age adjusted 1980 census population. For Grand Isle and Essex counties the data were aggregated with bordering counties to increase sample size: Franklin and Grand Isle were combined to produce the Grand Isle survival rates, and Caledonia, Essex and Orleans were combined for Essex survival rates. Five year survival rates were calculated. These rates were used to estimate the number of persons alive in 1980 who would live to 1985. For the 5 year intervals 1985-1990, 1990-1995, and 1995-2000, the rates were increased by the projected national rate of change developed by the U.S. Bureau of the Census for use in projecting the national population.[1]

b. Fertility Component.

The Vermont state and county fertility rates for the period 1975-80 were divided by the 1975-80 U.S. White rate to establish ratios. These ratios were multiplied by the projected U.S. White rates for periods 1980-85, 1985-90, 1990-95, and 1995-2000[1] to establish a set of projected state and county fertility rates. These rates were increased by approximately 2% to account for the impact of estimated in-migration of females aged 15-44 on the number of expected births in each projection period. The 1980 sex ratios of births for the state and counties were assumed to remain constant throughout the projection period.

c. Migration Component.

Vermont state and county residual net migration rates were calculated from the 1970 and 1980 census data and 1970-1980 vital statistics. The 1970 census college age-sex population cohorts 15-19 and 20-24 were adjusted by the same method used to adjust the 1980 census. In addition, the 1970 census was adjusted for an estimated 2% undercount overall. Separate undercount adjustments were made for the under 35, 35-64, and 65 and over cohorts.[2] The Windsor County population was adjusted for a greater undercount of that area.

Ten-year age and sex specific net-migration rates and total sex specific net-migration rates were calculated for the state and for each county. Both sets of 10-year rates

were multiplied by the appropriate population survived to 1990. The net number of migrants estimated by applying individual cohort rates and summing to total county migration was greater than that produced by applying the total rate for all ages. To stabilize some individual cohort rates, especially those of small and/or rapidly growing counties, and to bring the above two totals more closely toward agreement, the following revisions were made to the county rates:

(1) Where adjacent state cohorts had similar migration rates, but the county rates, based on smaller numbers, showed considerable fluctuation, the county data were grouped to produce larger cohorts. The following grouping was done for each county: male 0-14, 40-64, 75-85+ and female 0-19, 45-69, 75-85+. The other 5-year cohort rates were left unchanged, lest real differences in rates be obscured by grouping.

(2) Some counties with similar migration patterns were grouped to further stabilize cohort rates. Caledonia, Essex, and Orleans Counties were grouped and the 3-county cohort rates were used for these counties. Also Grand Isle, Lamoille and Orange were grouped and the 3-county rates used for Grand Isle and Orange. Better agreement between sum of cohorts and county total migration was achieved for Lamoille by using its own rates, as grouped in (1) above. The multi-county rates of Franklin, Rutland, Washington and Windsor worked well for Windsor County and were used.

(3) The end of the Vietnam War caused unusually large in-migration rates. Males who were 20-24 in 1970 and outside the country returned during the 1970's, and were counted as 30-34 year old in-migrants by the 1980 census. These migration rates are not likely to be sustained in succeeding decades. After consultation with the Census Bureau, which is assessing this problem nationwide, Vermont's male 30-34 migration rates were reduced by 30%.

Thus a set of age and sex specific migration rates was obtained in which the sum of age cohort migrants very nearly equalled the number of migrants calculated by using the total all-ages rate for the year 1990. These rates were also used for the 1990 to 2000 projection interval to produce the high series projections.

Since a continuation of the past relatively high migration rates is not a certainty, a low series projection was also made. The low series was based on a more conservative economic model for the state that was developed

from national economic projections.[3] According to this model, Vermont's labor force is projected to be about 310,000 in the year 2000. This represents a labor force participation rate that increases from 63% to 65% over the period 1980-2000, based on expected increases in female labor force participation. To arrive at a population projection that would result in this labor force, the 1970-1980 net in-migration rates for cohorts 0-74 years were halved, leaving the out-migration rates unchanged. All migration rates for the 75+ cohorts were left unchanged. An examination of the unpublished IRS migration flow data for 1980-81 showed that out-migration continued at about the same rate as during the late 70's, but that in-migration had slowed considerably. The resulting net all-ages migration rate used for the low series is approximately that of the 1975-1980 period as determined from the Census question on residence five years ago.

3. Interpolations for 1985 and 1995

The 1985 and 1995 projections were calculated using interpolation factors gained from the national projections. Factors were calculated for each age-sex cohort using the ratios[4]:

$$1985 \text{ factor} = \frac{\text{U.S. population 1985}}{\frac{1}{2} \text{ U.S. population (1980 + 1990)}}$$

$$1995 \text{ factor} = \frac{\text{U.S. population 1995}}{\frac{1}{2} \text{ U.S. population (1990 + 2000)}}$$

These factors were multiplied, respectively, by one-half the Vermont state and county populations (1980 + 1990) and (1990 + 2000) to obtain the Vermont state and county projections for 1985 and 1995.

4. Town Total Projections

Town total projections were produced by a ratio method after the county totals had been calculated by the above cohort-component method. In Vermont, the counties are composed of mutally exclusive municipalities called towns or cities. In this report the traditional term "town" includes the 9 cities and the unincorporated areas (towns, gores or grants).

For a given county, the proportional distribution of county population by towns was computed for the census years 1970 and 1980. For each town, the 1980 proportion was divided by the 1970 proportion and the result multiplied by the ratio of county

percent growth, 1980 to 1990 over 1970 to 1980. This product was then multiplied by the 1980 town distribution, yeilding the 1990 distribution. This distribution was adjusted to total to 1.000, then multiplied by the projected 1990 county total population to produce 1990 town total projections.

Observation of the results indicated that towns which had grown rapidly or had lost population, 1970-1980, tended to show extreme results, especially when projected to 2000. A second set of town projections was produced by multiplying the 1980 distribution by the 1990 county total. These two projections were averaged and are published as reasonable town projections. Fast growing towns are modulated in growth by this averaging, and towns having lost population during 1970-1980 will either have the loss slowed or reversed slightly. Towns growing at approximately the county rate of growth are relatively unchanged by averaging.

The 1985 town projections were interpolated by multiplying ½ (1980 + 1990) population of each town by the county ratio:

$$\frac{\text{1985 county population}}{\text{½ (1980 + 1990 county population)}}$$

This assumes that each town will experience the same share of its decade growth during the first half decade as does the county.

This procedure was repeated using 1980, 1990 and 2000 data to project towns to 2000 and interpolate back to 1995.

* The 15-19 cohorts replicate the figures published in VERMONT POPULATION PROJECTIONS, 1985-2000, October, 1983.
The additional detail is provided to meet the need for a population break at age 18.
